

Tangential trauma and haematoma. Application of liposuction combined with biological glue. [French]

Authors: Tropet Y., Garnier D., Vichard Ph.

Publication Date: 1990

Abstract:

The authors report an unconventional method of management in hematomas complicating tangential trauma. They use the application of liposuction within the first day, this procedure allows complete removal of the clots. It is associated with a biological glue sprayed all over the skin detachment. This simple operative technique is carried out under local anaesthesia and minimizes the recurrence of hematoma. The long term morphological result is satisfactory, avoiding the sequelae of conventional procedures.
