## **Abstract:**

The incompetent intestinal suture in the colon is one of the most frequent complications in emergency surgery. A great number of studies have found that the main way to improve the immediate postoperative result is to create optimal conditions for healing the intestinal wall. The results of clinical and experimental research of the drug "Tachocomb" for strengthening the intestinal anastomosis are described. It was shown that this technique allowed the mechanical strength of the anastomosis to be increased by stimulation of reparative processes in the intestinal suture and the microbial contamination to be reduced.
