Abstract:

Micro-Abstract Seroma formation and its sequelae cause complications and discomfort following mastectomy. In this retrospective study of 230 patients, patients underwent flap fixation after mastectomy using sutures or tissue glue. The results were compared to a group that had not been treated with flap fixation. The occurrence of seroma was significantly less in the group undergoing flap fixation with sutures. There were significantly fewer patients requiring seroma aspiration in both groups undergoing flap fixation.
